This looks better but there are lots of zero entries in there so let's get rid of them as we have no data for these.

Q. Complete the code below to filter countData to exclude genes (i.e. rows) where we have 0 read count across all samples (i.e. columns). Tip: What will rowSums() of countData return and how could you use it in this context?

```
countData = countData[rowSums(countData) > 0, ]

##Volcono Plot

plot( res\$log2FoldChange, -log(res\$padj) )

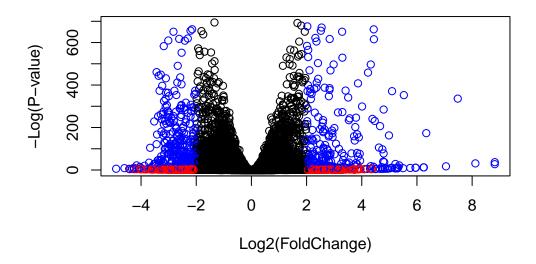

Q. Improve this plot by completing the below code, which adds color and axis labels

```
mycols <- rep("black", nrow(res) )
mycols[ abs(res$log2FoldChange) > 2 ] <- "red"

inds <- (res$padj < 0.01) & (abs(res$log2FoldChange) > 2 )
mycols[ inds ] <- "blue"

plot( res$log2FoldChange, -log(res$padj), col= mycols, xlab="Log2(FoldChange)", ylab="-Log(PoldChange)"</pre>
```

##Adding Gene Annotation > Q. Use the mapIDs() function multiple times to add SYMBOL, ENTREZID and GENENAME annotation to our results by completing the code below.

```

```

```

Q: What pathway has the most significant "Entities p-value"? Do the most significant pathways listed match your previous KEGG results? What factors could cause differences between the two methods?

The pathway that has the most significant Entities p-value is the cell cycle pathway with a p-value of 1.62E-4. Despite the pathways on our KEGG results have a significant p-values, these pathways does not match with the listed significant pathways on the Reactome website. However, some of the down-regulated pathways from our KEGG results show some slight similarities, but they do not appear to be matched. Some factors that could cause difference between the two methods is gene annotation differences, meaning that different databases could have gene annotations that are updated so its possible that some genes might be assigned to different pathways. Another factor would be both databases have different and various methods to run statistical tests and thresholds which could effect significant ranking of pathways.
